### COMPUTER TECHNOLOGY AND MULTIMEDIA OPERATING SYSTEM (MOS)

Unit 7

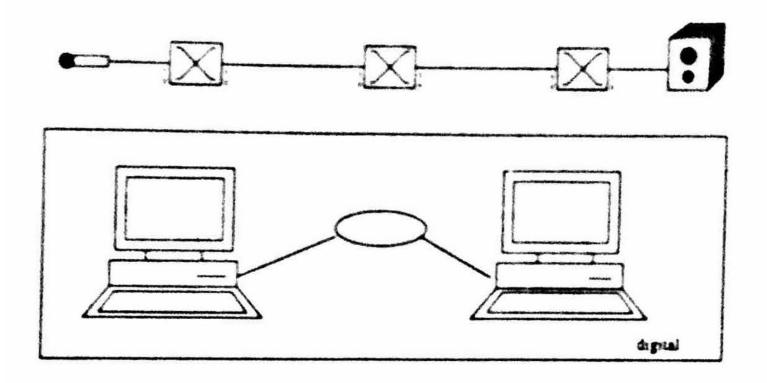

### 7.1. Communication Architecture

Local multimedia systems (i.e., multimedia workstations) trequently include a network interface (e.g., Ethernet card) through which they can communicate with each other. However, the transmission of audio and video cannot be carried out with only the conventional communication infrastructure and network adapters.

Until now, the solution was that continuous and discrete media have been considered in different environments, independently of each other. It means that fully different systems were built. For example, on the one hand, the analog telephone system provides audio transmission services using its original dial devices connected by copper wires to the telephone company's nearest end office. The end offices are connected to switching centers, called toll offices, and these centers are connected through high bandwidth intertoll trunks to intermediate switching offices. This hierarchical structure allows for reliable audio communication. On the other hand, using network adapters connected by copper wires to switches and routers.

Even today, professional radio and television studios transmit audio and video

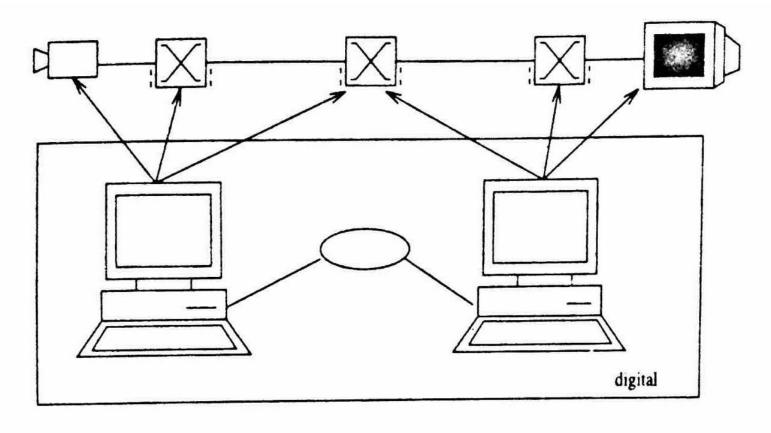

#### 7.1. Communication Architecture

Analog and digital environments without interaction

By using existing technologies, integration and interaction between analog and digital environments can be implemented. This integration approach is called the hybrid approach.

The main advantage of this approach is the high quality of audio and video and all the necessary devices for input, output, storage and transfer that are available. The hybrid approach is used for studying application user interfaces, application programming interfaces or application scenarios. The transmission techniques used in these cases are less important, although to meet the goal of full digital integration, this approach is not satisfactory.

Computer control of all audio-video components.

- This trend has emerged because with cooperative peers it is possible to asymptotically enhance the use of resources in sharing of data compared to the basic clientserver architecture.
- The need for distribution of data is wide and one could argue that it is as fundamental a building block as the message passing of the Internet.
- As an answer to this need a new scalable architecture is introduced: Hybrid Communication Architecture (HCA), which provides both data sharing and message passing as communication primitives for applications.

- HCA can be regarded as an abstraction layer for communication which is further encapsulated by a higher-level middleware.
- HCA is aimed at general use, and it is not designed for any particular application.
- One key idea is to combine data sharing with streaming since together they enable many applications not easily implementable with only one of these features.
- For example, a game application could share the game world state between clients and modify it by using streaming. The other distinctive feature of the system is the use of knowledge of the physical network topology in the optimization of the communication. With a feasible business model, faulttolerance, and security features, HCA is aimed eventually for real-life adoption.

The following interfaces and protocols form the skeleton of the HCA framework:

- Client interface is used by applications on top of HCA,
- DLL interface divides the client side implementation of HCA into dynamically and statically linked parts,
- Context interface passes information from the execution environment to the application,
- Security interface provides an access to cryptographic functions,
- OSLib interface provides an abstraction layer for different operating systems,
- Inter-domain protocol is used by communication nodes of the HCA network,
- Intra-domain protocol is used by communication nodes of the same domain as explained later.

In a normal configuration, multiple applications with their HCA client interface static implementations and a single local node implementation are located on the same **client machine** at the edge of the HCA overlay network.

The **client machine** can be, for example, the user's home computer or office workstation which is shut down every now and then. The local node communicates with the nearest communication node using the inter-domain protocol.

This node probably resides on a different machine typically administered by a service provider organization or it could be located in a company intranet server.

The HCA overlay network is formed by many communication nodes structured in the form of hierarchical domain tree.

The nodes are connected by the inter-domain protocol and typically reside in servers that are continuously online. Clients and persistence servers can be thought of residing at the edge of the overlay network.

Client interface, OSLib, Context interface and Security interface form together an operating-system- and hardware-independent platform for components on top of HCA.

#### **Client Interface**

The HCA Client interface is the only part of the communication architecture visible to applications and higher-level layers of the middleware.

Because HCA is intended to be programming language neutral, there are language mappings of the client interface to each programming language supported.

The implementation of the client interface is normally divided to statically and dynamically linked parts so that it is possible to change the implementation without recompiling applications.

#### **DLL Interface and Local Node Implementation**

HCA DLL (Dynamic link library) interface is an operating-system dependent application programming interface (API) for wrapping the local communication node to a separate process running on the client machine.

The DLL implementation shares the local communication node between multiple client processes and implements the communication between client processes and the local communication node process using fast inter-process communication, shared memory or other facilities provided by the operating system.

#### **OSLib**

OSLib programming interface provides a systemwide hardware abstraction layer (HAL) for preventing the components of HCA of having unnecessary dependencies to particular operating system or hardware. With this modularization in implementations we gain the easy portability of HCA implementations over different platforms.

#### **Context Interface**

Context interface is intended to pass information from the execution platform to the program. For example, communication node implementations can use it to read the configuration information of the node

#### **Security Interface**

Security interface contains a uniform interface for typical cryptographic algorithms. An abstract interface for both public key and secret key methods are specified.

#### **Inter-domain Protocol**

Inter-domain protocol is used between all communication nodes to form the overlay network of HCA

#### **Intra-domain Protocol**

Each domain can use their own intra-domain protocol for coordination of the nodes inside the domain.

Nodes must implement the intra-domain protocol used by their enclosing domain. Small domains do not necessarily need an intra-domain protocol for managing nodes because it can be achieved by configuring each node manually.

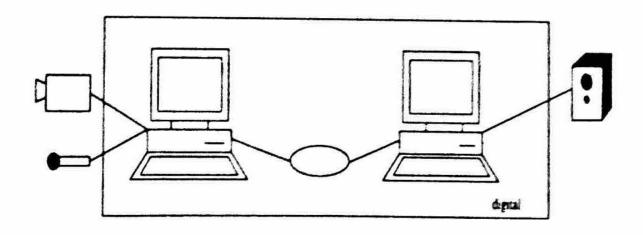

Digital systems are designed to store, process, and communicate information in digital form.

They are found in a wide range of applications, including process control, communication systems, digital instruments, and consumer products.

The digital computer, more commonly called the *computer*, is an example of a typical digital system.

#### Connection to Workstations

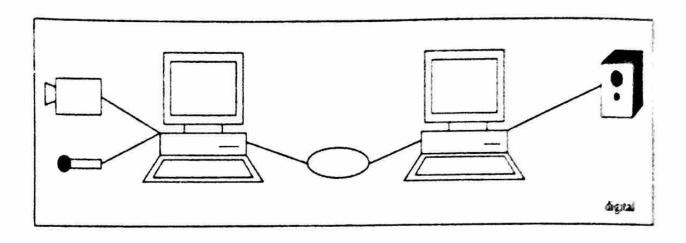

In digital systems, audio-video devices can be connected directly to the computers (workstations) and digitized audio-video data are transmitted over shared data networks, Audio-video devices in these systems can be either analog or digital. Figure 8.5 shows an integrated system structure with analog devices and A/D and D/A interfaces. Figure 8.6 shows an integrated system structure with digital end-system devices and interfaces.

Integrated (with respect to hardware) system structure with analog endsystem devices and A/D and D/A interfaces.

An example of a digital system is the *Etherphone* system from Xerox PARC [Swi87]. A digital audio communication was demonstrated over an Ethernet, although not in a fully integrated form, i.e., the audio was not processed in the main memory.

Another example is an early project by AT&T in Naporville, which considered a similar system architecture to a Etherphone [LL89, LBH+90]. Here, a computer was directly connected to a Fast Packet Switching network. The processing of continuous media in the computer was allowed through extensions of the UNIX operating

Integrated (with respect to hardware) system structure with digital end system devices and interfaces.

A computer manipulates information in digital, or more precisely, binary form. A binary number has only two discrete values — zero or one.

#### 7.2. Multimedia Workstation

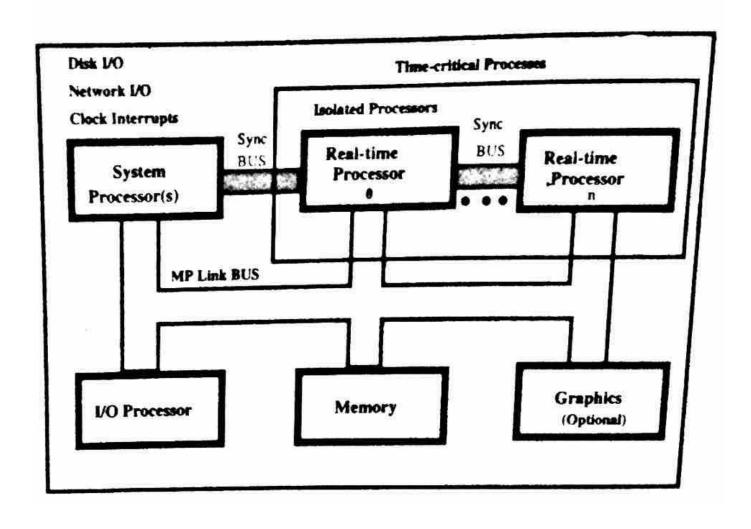

Current workstations are designed for the manipulation of discrete media information. The data should be exchanged as quickly as possible between the involved components, often interconnected by a common bus. Computationally intensive and dedicated processing requirements lead to dedicated hardware, firmware and additional boards. Examples of these components are hard disk controllers and FDDI-adapters.

#### 7.2. Multimedia Workstation

A multimedia workstation is designed for the simultaneous manipulation of discrete and continuous media information. The main components of a multimedia workstation are:

- Standard Processor(s) for the processing of discrete media information.
- Main Memory and Secondary Storage with corresponding autonomous controllers.
- Universal Processor(s) for processing of data in real-time (signal processors).
- Special-Purpose Processors designed for graphics, audio and video media (containing, for example, a micro code decompression method for DVI processors) [Rip89, Tin89, Lut91].
- Graphics and Video Adapters.
- Communications Adapters (for example, the Asynchronous Transfer Mode Host Interface [TS93].
- Further special-purpose adapters.

#### 7.2. Multimedia Workstation

The operating system provides a comfortable environment for the execution of programs, and it ensures effective utilization of the computer hardware.

The OS offers various services related to the essential resources of a computer: CPU, main memory, storage and all input and output devices.

In multimedia applications, a lot of data manipulation (e.g. A/D, D/A and format conversion) is required and this involves a lot of data transfer, which consumes many resources.

The integration of discrete and continuous multimedia data demands additional services from many operating system components.

The major aspect in this context is *real-time* processing of continuous media data.

#### Issues concerned:

- Process management: a brief presentation of traditional real-time scheduling algorithms.
- File systems: outlines disk access algorithms, data placement and structuring
- Interprocess communication and synchronization
- Memory management
- Database management
- Device management

Process management must take into account the timing requirement imposed by the handling of multimedia data.

Concerns in process management (Scheduling):

	Traditional OS	MM OS
Timing requirement	No	Yes
Fairness	Yes	Yes

Single components are conceived as resources that are reserved prior to execution to obey timing requirements and this *resource reservation* has to cover all resources on a data path.

The communication & synchronization between single processes must meet the restrictions of real-time requirements and timing relations among different media.

Memory management has to provide access to data with a guaranteed timing delay and efficient data manipulation functions. (e.g. should minimize physical data copy operations.)

Database management should rely on file management services

A real-time process is a process which delivers the results of the processing in a given time-span.

The main characteristic of real-time systems is the correctness of the computation.

- Errorless computation
- The time in which the result is presented

Speed and efficiency are not the main characteristic of real-time systems. (e.g. the video data should be presented at the right time, neither too quickly nor too slowly)

Timing and logical dependencies among different related tasks, processed at the same time, must also be considered.

#### **Deadlines:**

A deadline represents the latest acceptable time for the presentation of a processing result.

#### Soft deadline:

- a deadline which cannot be exactly determined and which failing to meet does not produce an unacceptable result.
- Its miss may be tolerated as long as (1) not too many deadlines are missed and/or (2) the deadlines are not missed by much.

#### 🐧 Hard deadline:

- a deadline which should never be violated.
- Its violation causes a system failure.
- Determined by the physical characteristics of real-time processes.

#### **Characteristics of real time systems**

The necessity of deterministic and predictable behavior of real-time systems requires processing guarantees for time-critical tasks.

A real-time system is distinguished by the following features:

- Predictably fast response to time-critical events and accurate timing information:
- A high degree of schedulability: to meet the deadlines.
- Stability under transient overload: critical task first.

#### Real time and multimedia

The real-time requirements of traditional real-time scheduling techniques usually have a high demand for security and fault-tolerance. (Most of them involve system control.)

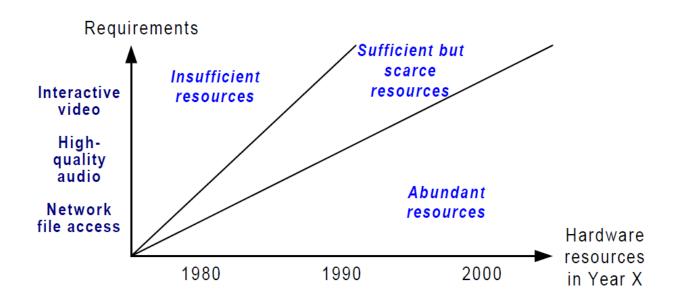

### 7.5. Multimedia Real Time System

Real-time requirements of multimedia systems:

- The fault-tolerance requirements of multimedia systems are usually less strict than those of real-time systems that have a direct physical impact.
- For many multimedia system applications, missing a deadline is not a severe failure, although it should be avoided. (e.g. playing a video sequence)
- In general, all time-critical operations are periodic and schedulability considerations for periodic tasks are much easier.
- The bandwidth demand of continuous media is usually negotiable and the media is usually scalable.

#### **Resource management**

Multimedia systems with integrated audio and video processing are at the limit of their capacity even with data compression and utilization of new technology. (Demand increases drastically.)

No redundancy of resource capacity can be expected in the near future.

In a multimedia system, the given timing guarantees for the processing of continuous media must be adhered to along the data path.

The actual requirements depend on (1) the type of media and (2) the nature of the applications supported.

The shortage of resources requires careful allocation.

The resource is first allocated and then managed.

At the connection establishment phase, the resource management ensures that the new 'connection;' does not violate performance guarantees already provided to existing connections.

Applied to OS, resource management covers the CPU (including process management), memory management, the file system and the device management.

The resource reservation is identical for all resources, whereas the management is different for each.

#### Resources

A resource is a system entity required by tasks for manipulating data.

A resource can be active or passive.

- Active resource:
  - e.g. the CPU or a network adapter for protocol processing;
  - it provides a service.
- Passive resource:
  - e.g. main memory, communication bandwidth or file systems;
  - It denotes some system capability required by active resources.

#### Resources

A resource can be either used exclusively by one process at a time or shared between various processes.

Active ones are often exclusive while passive ones can usually be shared.

Each resource has a capacity in a given time-span. (e.g. processing time for CPU, the amount of storage for memory and etc.)

For real-time scheduling, only the temporal division of resource capacity among real-time processes is of interest.

#### Requirements

The requirements of multimedia applications and data streams must be served.

The transmission/processing requirements of local and distributed multimedia applications can be specified according to the following characteristics:

- Throughput: Determined by the needed data rate of a connection to satisfy the application requirements.
- Delay "at the resource" (local): The maximum time span for the completion of a certain task at this resource.
- End-to-end delay (global): The total delay for a data unit to be transmitted from the source to its destination.
- Jitter: Determines the maximum allowed variance in the arrival of data at the destination.
- Reliability: Defines error detection and error correction mechanisms used for the transmission and processing of multimedia tasks.
  - How to handle errors: Ignored, indicated and / or corrected.
  - Retransmission may not be acceptable for time critical data.
- These requirements are known as Quality of Service (QoS) parameters.

### **Components and phases**

Resource allocation and management can be based on the interaction between clients and their respective resource managers.

The client selects the resource and requests a resource allocation by specifying its QoS specification.

The resource manager checks its own resource utilization and decides if the reservation request can be served or not.

Performance can be guaranteed once it is accepted.

#### Components and phases (cont...)

Phases of the resource reservation and management process

#### 1.Schedulability

 The resource manager checks with the given QoS parameters (e.g. throughput and reliability).

#### 2.QoS calculation

 The resource manager calculates the best possible performance (e.g. delay) the resource can guarantee for the new request.

#### 3.Resource reservation

 Allocates the required capacity to meet the QoS guarantees for each request.

#### 4. Resource scheduling

 Incoming messages (i.e. LDUs) from connections are scheduled according to the given QoS guarantees.

#### **Allocation Scheme**

Reservation of resources can be made either in a pessimistic or optimistic way:

The pessimistic approach avoids resource conflicts by making reservations for the worst case. (It's very conservative.)

The optimistic approach reserves resources according to an average workload only.

### **Allocation Scheme (cont..)**

	Pessimistic	Optimistic
	approach	approach
Account	Worst case	Average case
for		
QoS	Guaranteed	Best effort
Utilization	Low	High
Remarks		May need a
		monitor to detect
		overload
		situation and act

#### Continuous media resource model

A model is frequently adopted to define QoS parameters and the characteristics of the data stream.

It is based on the model of linear bounded arrival process (LBAP).

A distributed system is decomposed into a chain of resources traversed by the messages on their end-to-end path.

The data stream consists of LDUs (messages). Various data streams are independent of each other.

The model considers a burst of messages consists of messages that arrived ahead of schedule.
